

Cell Cycle

Outline

Cell growth as the driver for cell cycle (in microbes):
coordination of growth and division

A basic principle organizing cell cycle control: why cyclin-dependent
kinase activity must oscillate

Very messy regulatory machinery that provides the oscillations:
two potentially independent oscillatory mechanisms working in tandem

Chemical-kinetic modeling (in collaboration with John Tyson)

Coordination of growth and division:

Hartwell and Unger 1977:

The minimum time for the cell division cycle is significantly less than the mass
doubling time.

Note: mass increase (ribosomes, etc) is approximately exponential
with increasing cell size. Thus the 'mass doubling time'.

Growth and division are entrained because small cells are significantly less likely
to initiate the cell division cycle than larger cells.

Cell Cycle

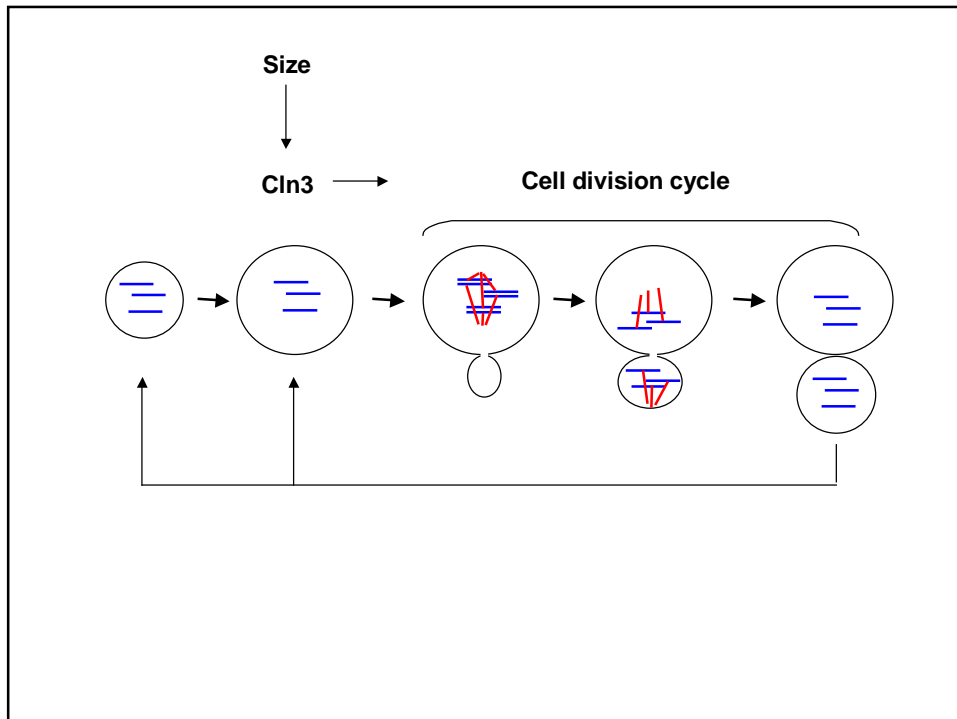

Coordination of growth and division:

Smaller cells are less likely to initiate the cell division cycle; the setpoint for the minimum size can be modulated by Cln3 (initiator cyclin) levels.

The mechanism remains unsolved.

Do cells measure nuclear/cytoplasmic ratios?

Is nuclear Cln3 a part of this measurement ratio?

Cell Cycle

A good idea:

Make a biochemical oscillator, so that some enzyme activity **X** goes up and down.

Set up each bit of cell cycle machinery as two-step processes.

Then, connect up the cell division cycle machinery in the following way:

Step A ← **X** —| Step B

B-type cyclin: the oscillating component (Tim Hunt)

-  : Origins of DNA replication loaded
-  : Origins of DNA replication in use
-  : Origins of DNA replication unloaded

Cell Cycle

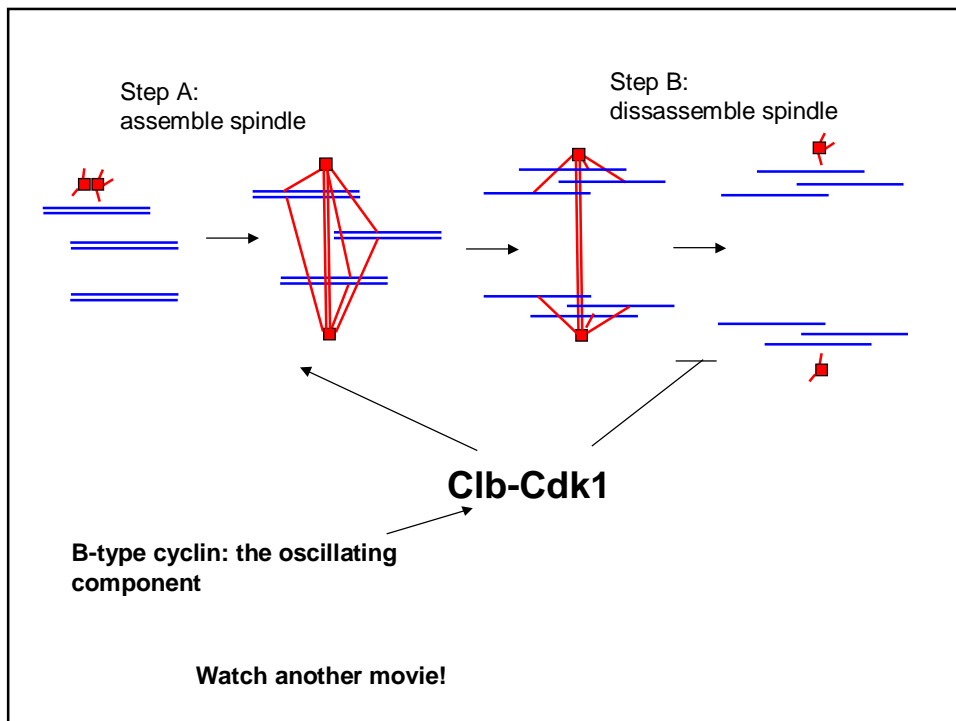

One part of regulation of origin loading
by Cdk activity: removing Mcm proteins from the nucleus

The Mcm complex is loaded at origins before firing.
It is essential for origin function. Cdk phosphorylation of
the Mcm complex results in its exclusion from the nucleus.

See the movie:

Note nuclear fluorescence only right after cell division.

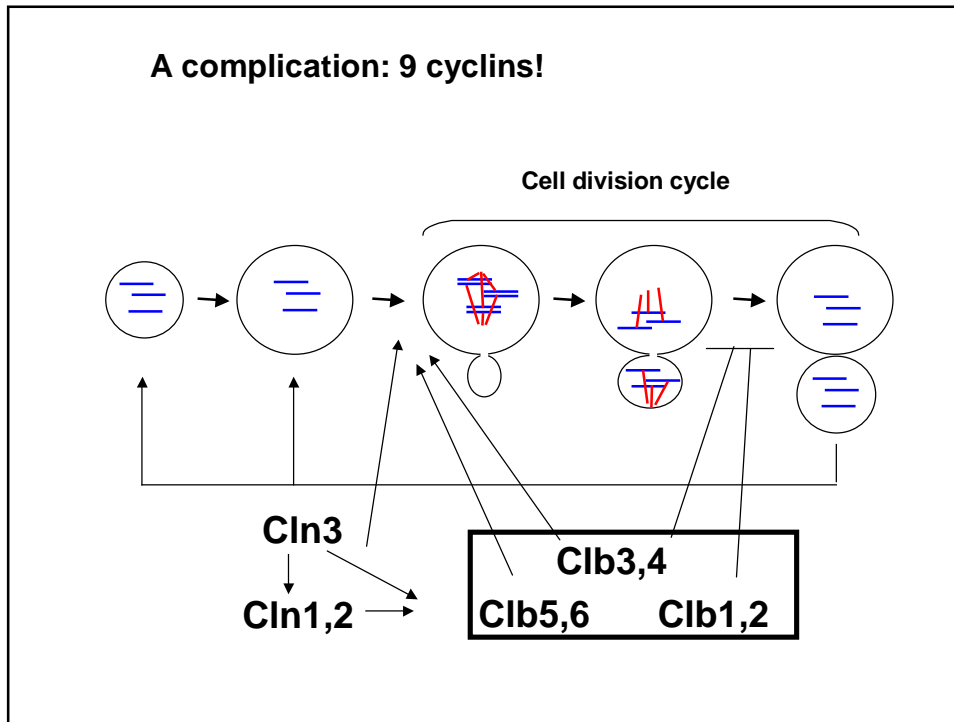

(Subtle point: fluorescence lasts a bit longer in daughter
nuclei than in mother nuclei)

Cell Cycle

Cell Cycle

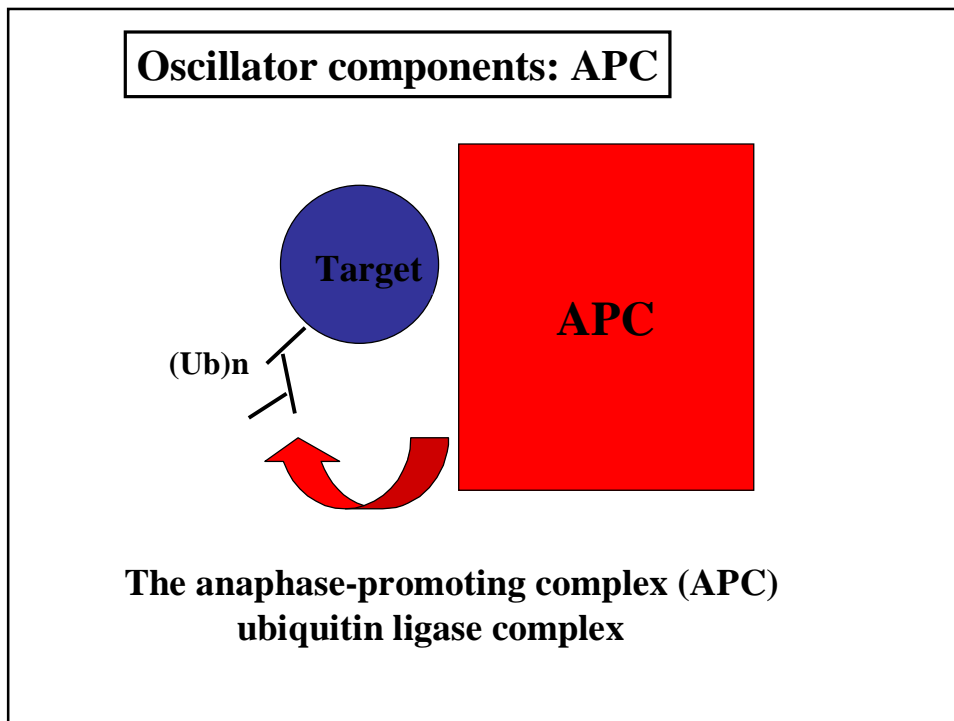

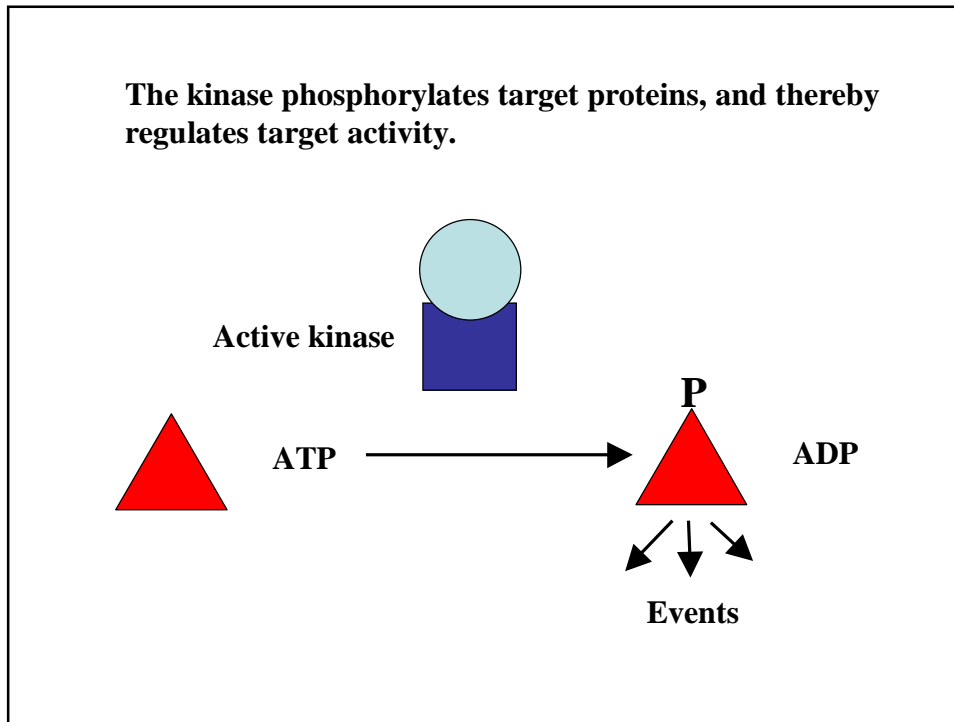

Cell Cycle

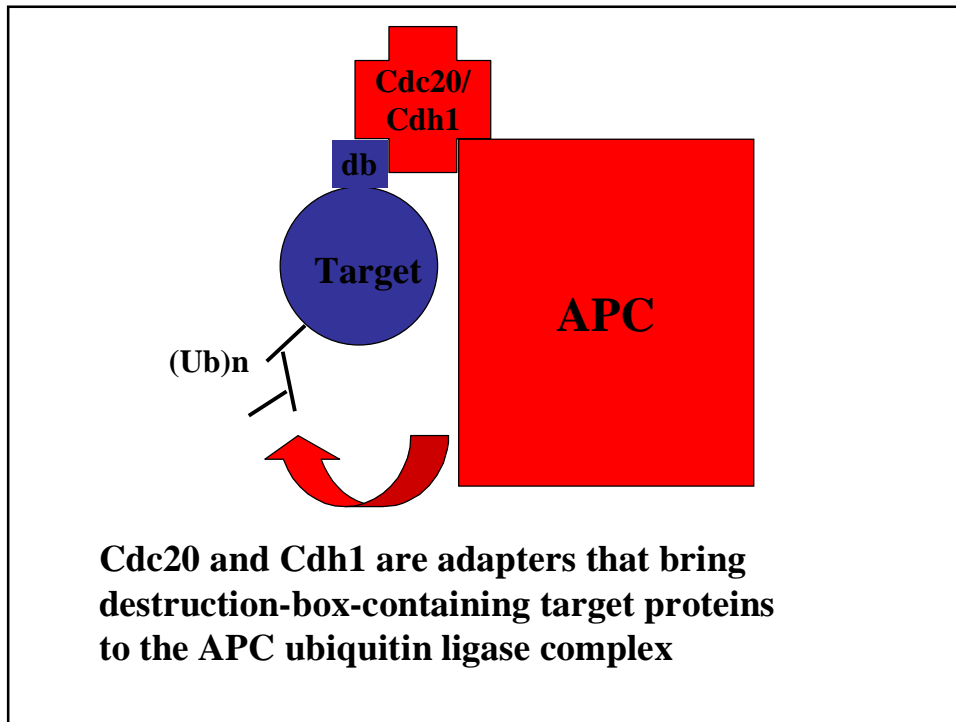

Oscillator components: cyclins

Cyclins work by activating a kinase.

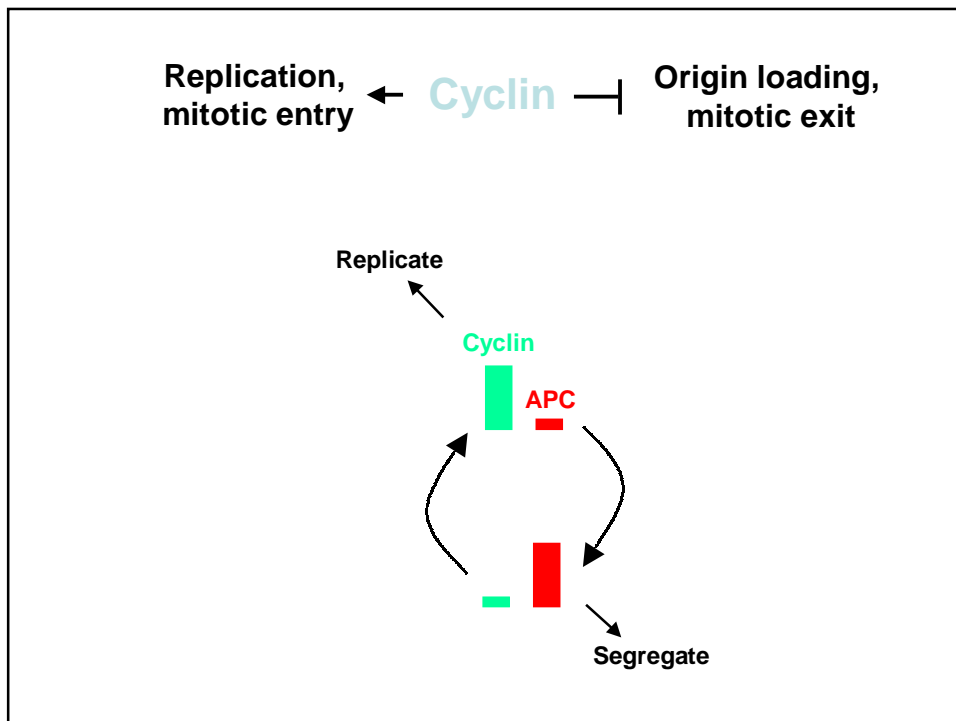

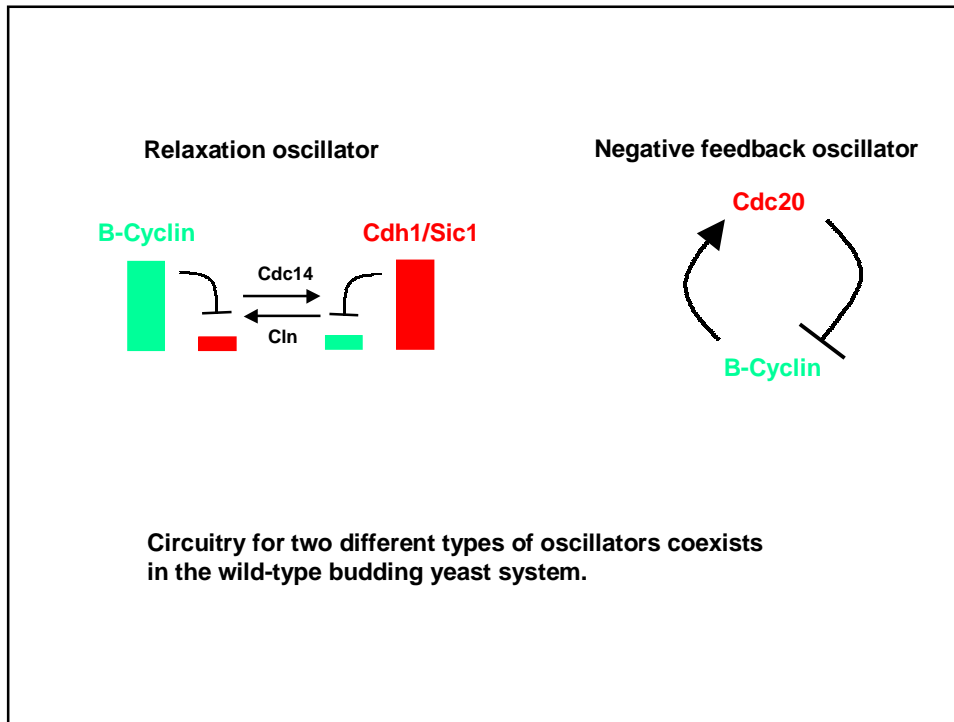

Cell Cycle

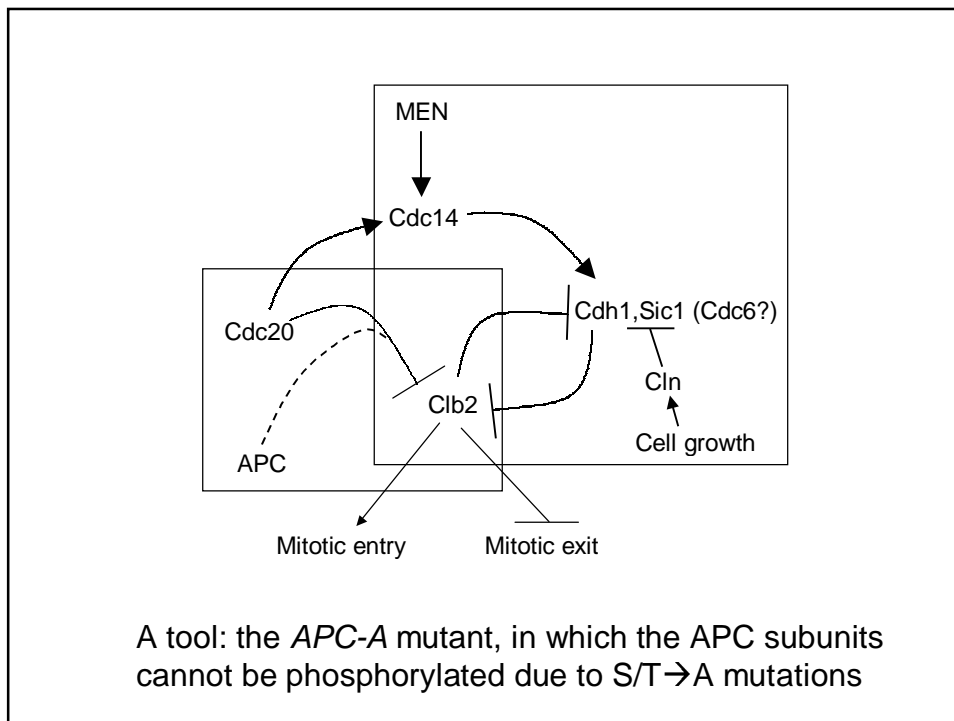

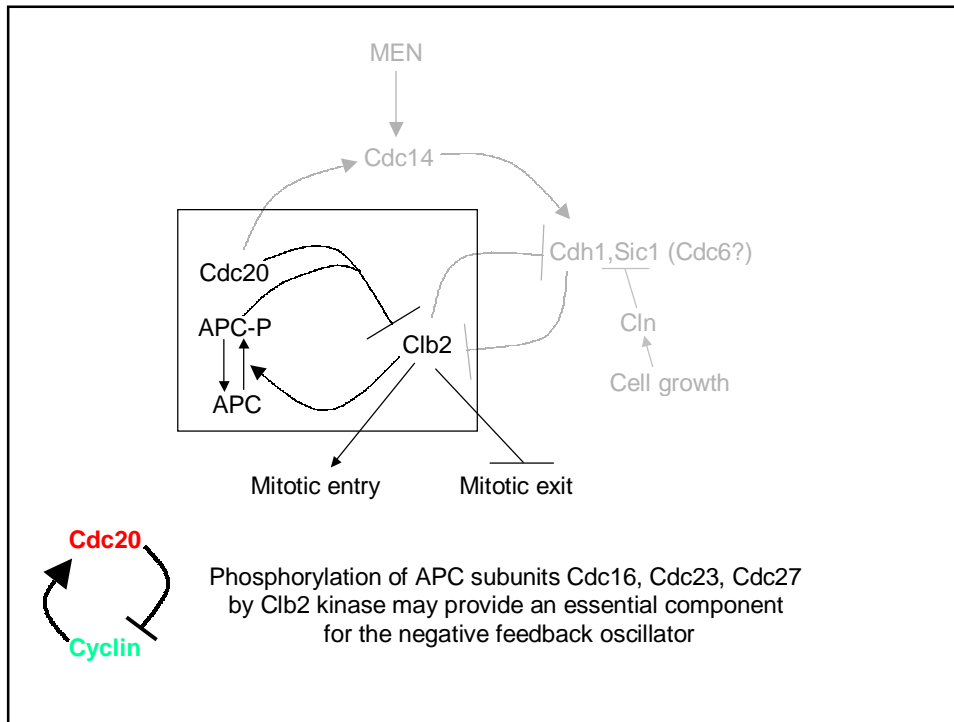

Cell Cycle

Parameter	Effect of change	Change
kdb2p	Increase Cdc20 -dependent Clb2 degradation	Up 10X
ks20'	Increase constitutive CDC20 transcription	Up 20X
ks20"	Increase Clb2-regulated CDC20 transcription	Up 4X
kd20	Decrease Cdc20 degradation	Down 8X
ka20'	Increase Phospho-APC-independent Cdc20 activity	Up 7X
ksc1'	Increase constitutive SIC1 transcription	Up 8X
ksc1"	Increase Swi5-regulated SIC1 transcription	Up 90X
kaswi	Increase Swi5-regulated SIC1 transcription	Up 10X
Jiswi	Increase Swi5-regulated SIC1 transcription	Up 90X

cdh1 APC-A model: test systematic parameter variations for 'suppression' of 'inviability'

**Why would cells have two functional oscillators?
Maybe they function at different times...**
