Astrophys. J. **602**, 892 (2004)

Astrophys. J. **638**, 382 (2006)

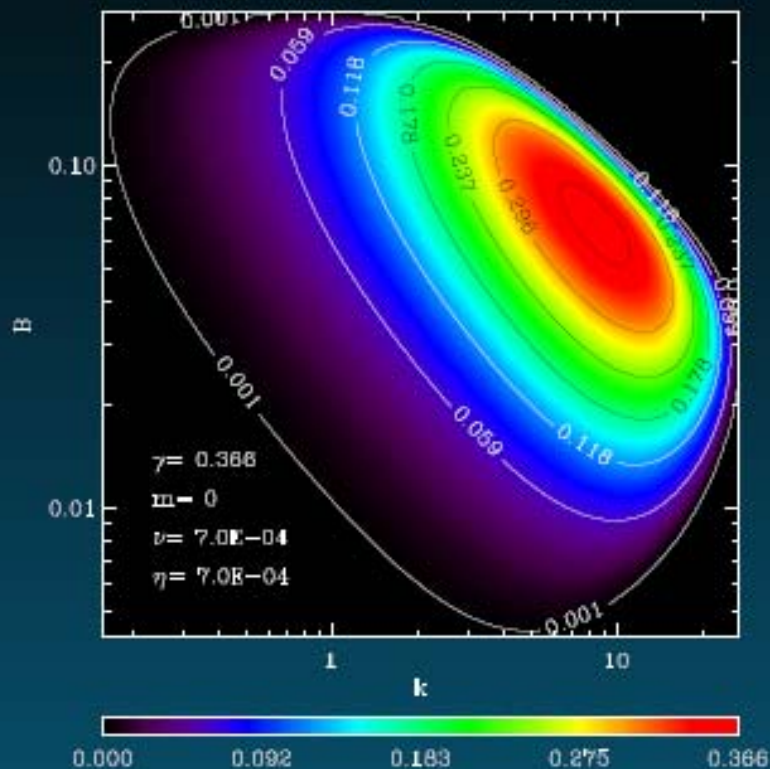

Ideal MRI Modes

No inflow in the basic state

- $m = 0$ is the most unstable global mode
- Quenching by the magnetic tension
- Saturation: $\gamma_{\max} \rightarrow r_1/2 |d\Omega/dr|_{r_1}$

Dissipative MRI Modes

- Modes slightly modified by inflow & dissipation
- Growth rates globally reduced
- **Damping of the small-scale modes**

Wall Modes

- Wall modes solutions of the linear system too
- γ too large for the free energy available and large range of k unstable
- Ideal case: γ scales linearly with k and increases rapidly with B_0
- Significant flux of energy through the boundaries to feed these modes
- Inflow, curvature and Coriolis force non crucial

Cartesian Wall Modes in MHD

Magnetic field destabilizes the wall modes

$$u_z'' - 2 \frac{\omega_a^2}{\chi^2 + \omega_a^2} \frac{\chi'}{\chi} u_z' - \left[k^2 + \frac{\chi''}{\chi} - 2 \frac{\omega_a^2}{\chi^2 + \omega_a^2} \left(\frac{\chi'}{\chi} \right)^2 \right] u_z = 0$$

Singularity when $\gamma = 0$ and $\omega = -k_x U_0 \pm \omega_a$
