pretty sure

# Our signatures of Majoranas

Good starting point: high mobility InSb anowires, strong SOI, induced SC

Zero bias peak (ZBP) onsets at  $B \sim 100$  mT

$$E_z \sim 150 \mu\text{eV}, \text{ so } \boxed{E_z \sim \Delta}$$

ZBP remains stuck to zero bias over significant range of  $B$  ( $\Delta E_z \sim 0.5\text{-}1.5$  meV)

ZBP persist over large gate ranges for all gates, but gate tuning is required

*As expected for an edge state of a topological superconductor*

ZBP vanishes when  $B$  is aligned with  $B_{\text{SO}}$

*Suggests that spin-orbit interaction is required to observe ZBP*

ZBP robust in both gate and  $B$  not observed in two N-NW-N devices

*Suggests that superconductivity is an ingredient*

Persistent ZBP reproduced in four N-NW-S devices and three cryostats

Now, also reproduced by Hugh Churchill at Harvard (Marcus group, wires from Lund)

## Follow-ups for immediate future

Increase ZBP height from 5% to expected  $2e^2/h$

*Make induced gap hard rather than soft (states within gap)*

*Lower temperature*

Observe the closing of the induced gap

*Vary the number of occupied subbands underneath superconductor*

Map out ZBP phase diagram in  $E_Z$  and  $V_{\text{gate}}$

*Relation between gate voltage and chemical potential*

*Probe ZBP through a real QPC (from ZBP to zero bias dip)*

Split ZBP by bringing two edge states together

*Vary superconductor segment length*

*Improve gate coupling*

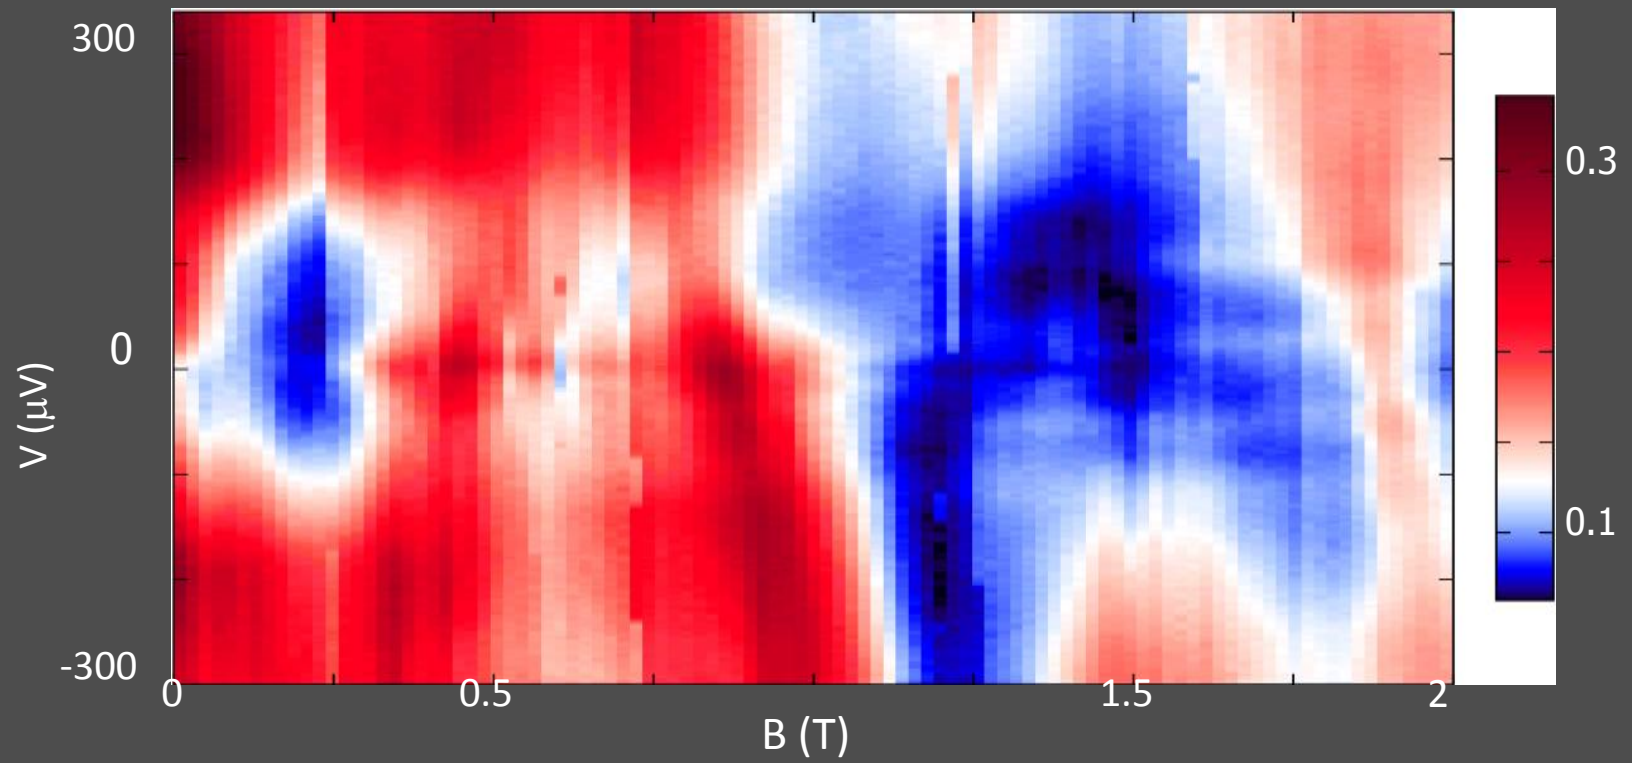

# Three-terminal geometry, improved materials

**States that run parallel to zero-bias peak**

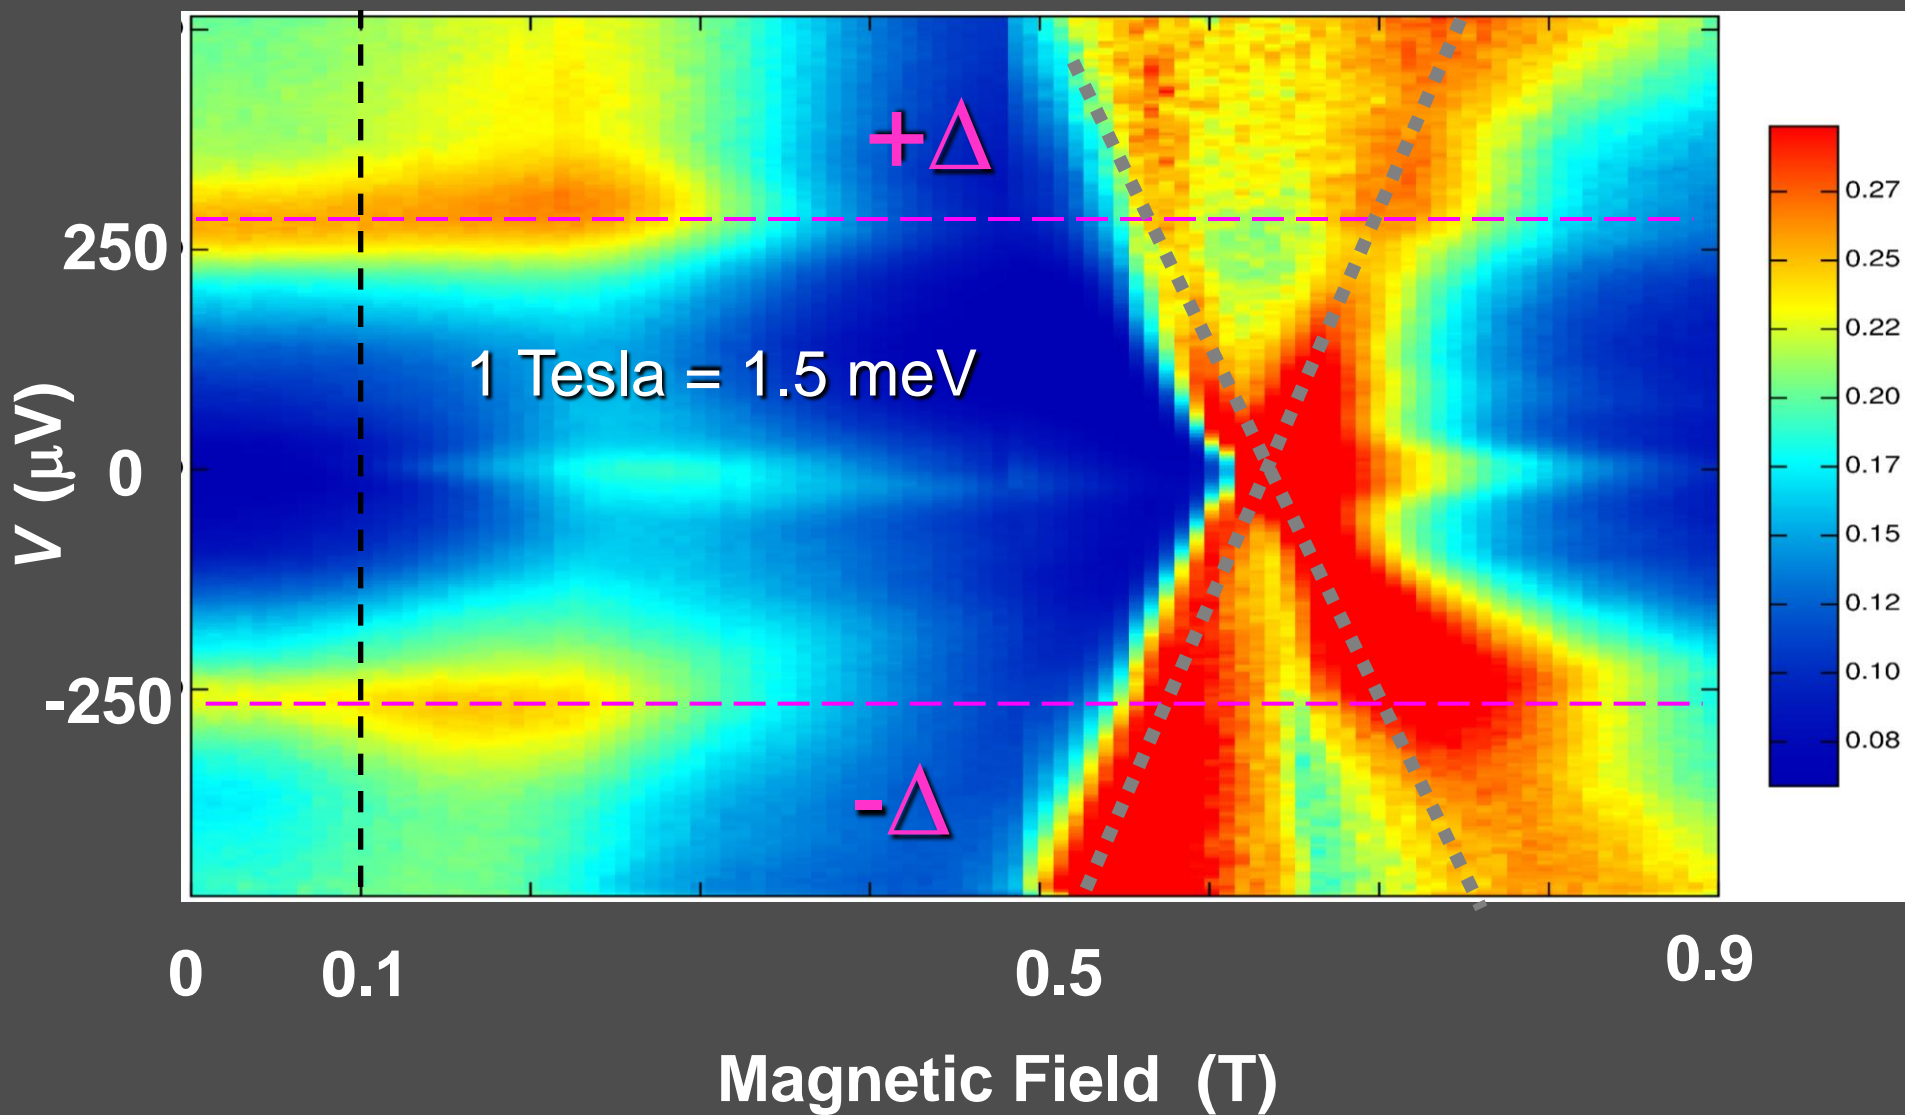

## Another device: same effects observed

# Another example

Peak onset  $E_z \sim \Delta$

# N2-S

UBG=0V; UFG1-3=-2.5V; BG1-3=-5V; LFG1=-2.9V; LFG2=1.3V; LFG3=2.7V  
LBG=2.5V

## Observation of zero bias peak
