

Modeling quorum sensing - why so many feedbacks?

Ned Wingreen, Princeton

KITP August 6, 2014

Quorum sensing network in *V. harveyi*

QS network has many internal feedbacks

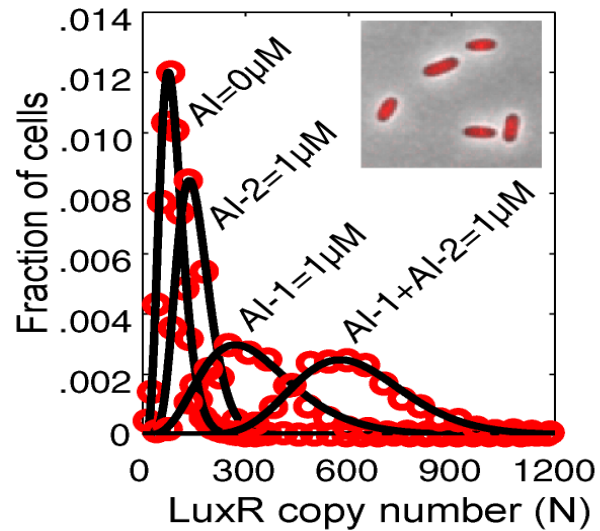

Rutherford *et al.*, *Genes & Dev* (2011)
Shao & Bassler, *Mol Micro* (2012)

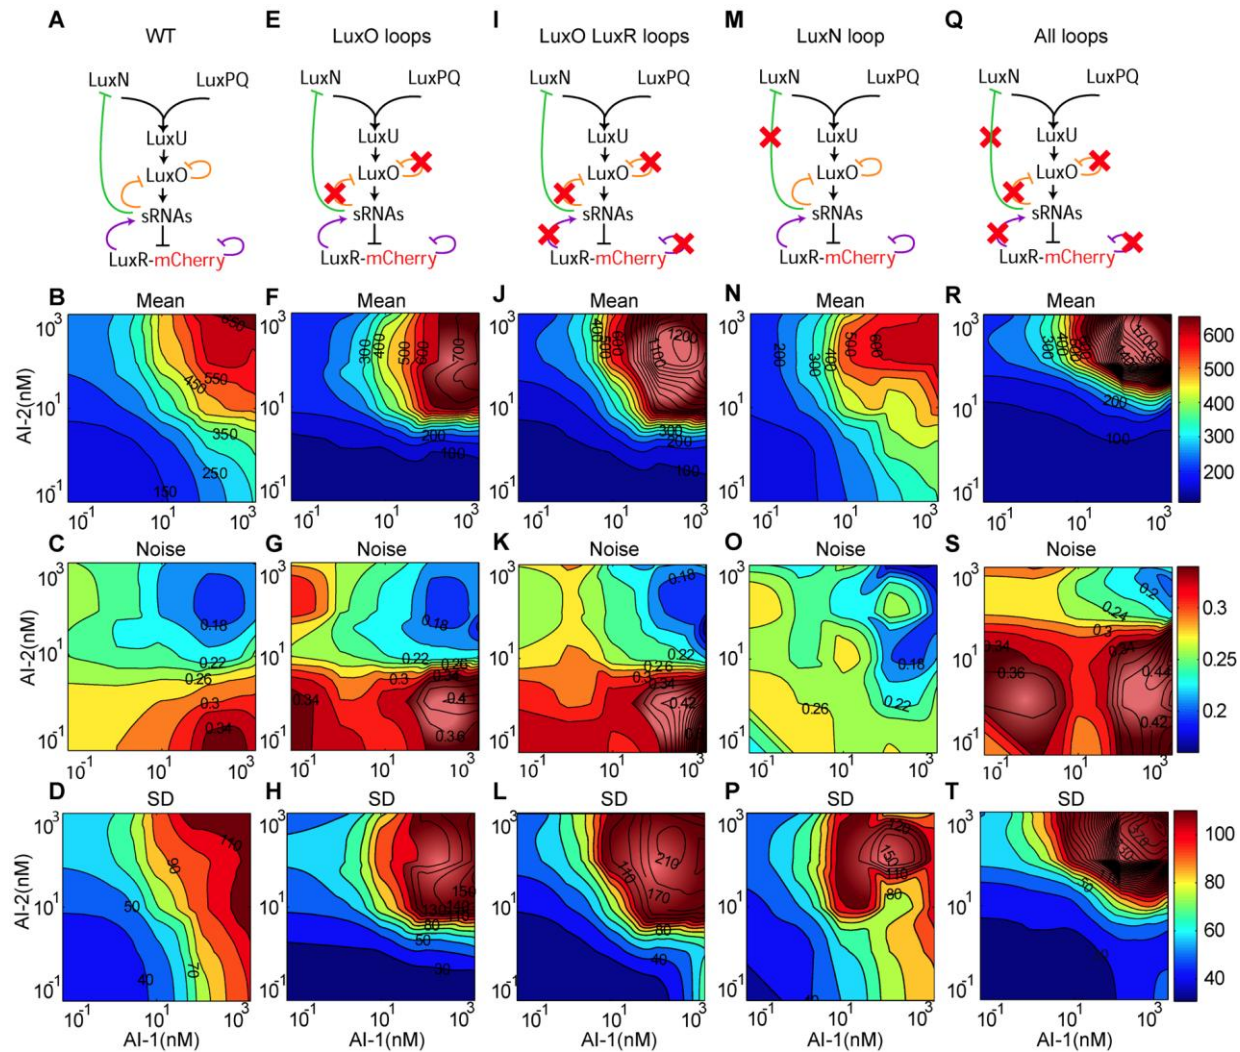

Engineered reporter strains

Single-cell measurements

Each feedback does something...

LuxN feedback regulates receptor ratio

WT

Low Cell Density

WT

High Cell Density

Core feedbacks have little effect on noise

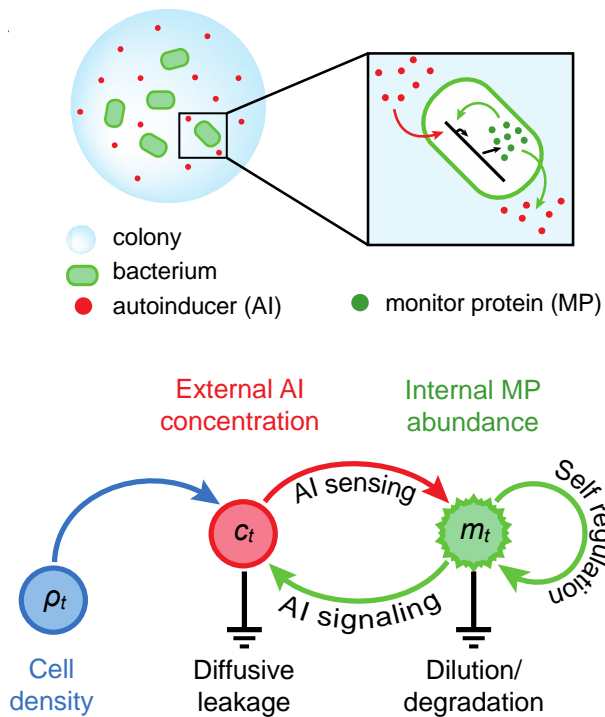

Feedback by LuxR controls input-output relation

LuxR feedback increases AI input dynamic range and decreases LuxR output dynamic range.

Quorum-sensing feedbacks and mutual information

TF-based regulation

sRNA-based regulation

Feedbacks can optimize available information about cell density

Mutual information

MI increase due to feedbacks

b = protein “burst size”
 g_+ = feedback inhibition

Feedback from LuxR speeds Qrr production at HCD → LCD transition

Tu *et al.*, *Mol Micro* (2008)

Simple model for network dynamics

E.g. equations for $Qrrs$ and $luxR$ / $LuxR$:

$$\begin{aligned} \frac{d[Qrr]}{dt} &= Q * V_{tscr} \left(\frac{[LuxO\sim P]}{K_M^{OP} + [LuxO\sim P]} \right) \left(\frac{K_I^A}{K_I^A + [AphA]} \right) \left(\frac{K_M^R + A_R^Q [LuxR]}{K_M^R + [LuxR]} \right) \\ &\quad - k_{qn}[Qrr][luxN] \\ &\quad - k_{qo}[Qrr][luxO] \\ &\quad - k_{qr}[Qrr][luxR] \\ &\quad - k_{qa}[Qrr][aphA] \\ \frac{d[luxR]}{dt} &= V_{tsla} \left(\frac{K_M^A + A_A^R [AphA]}{K_M^A + [AphA]} \right) \left(\frac{K_I^R}{K_I^R + [LuxR]} \right) - k_{qr}[Qrr][luxR] - D_{mRNA}[luxR] \\ \frac{d[LuxR]}{dt} &= V_{prot}[luxR] - D_{prot}[LuxR] \end{aligned}$$

Simulate transitions:

LCD \rightarrow HCD and HCD \rightarrow LCD.

Model results for HCD→LCD transition

Qrrs

AphA

luxR / LuxR

Network design accelerates HCD→LCD response:

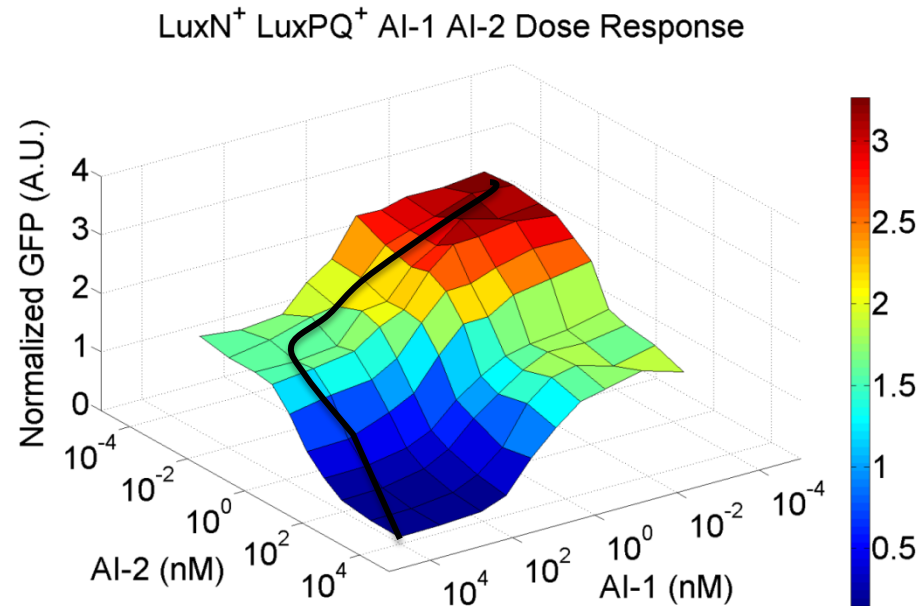

- Multiple Qrrs
- LuxR co-activation of Qrrs
- Qrr repression of LuxO
- Cap on total LuxR
- Negative feedback via AphA limits Qrr accumulation

So why is the QS network so complex?

Lifecycle of bacteria in a biofilm

Courtesy of Davis Lab at Binghamton Univ.

- Multiple autoinducers and feedbacks may allow multi-stage developmental program.
- Feedbacks can help cells focus on most relevant signal and respond quickly to HCD → LCD transitions.

Summary

- **AphA/LuxR are the LCD/HCD master regulators in the Vibrio quorum-sensing network.**
- **Complex network architecture allows:**
 - **Increased information on cell density**
 - **“Attention” to specific signals**
 - **Fast response to HCD → LCD transition**

The Microbiome, metagenomics, and clustering-free 16S RNA analysis

Ned Wingreen

Mikhail Tikhonov

Robert Leach

Princeton University

Outline

- The Microbiome
- 16S RNA metagenomics
- Clustering-free analysis of 16S data
- Sequence similarity vs. dynamical similarity
- Conclusions

The Human Microbiome

Impact of the Microbiome

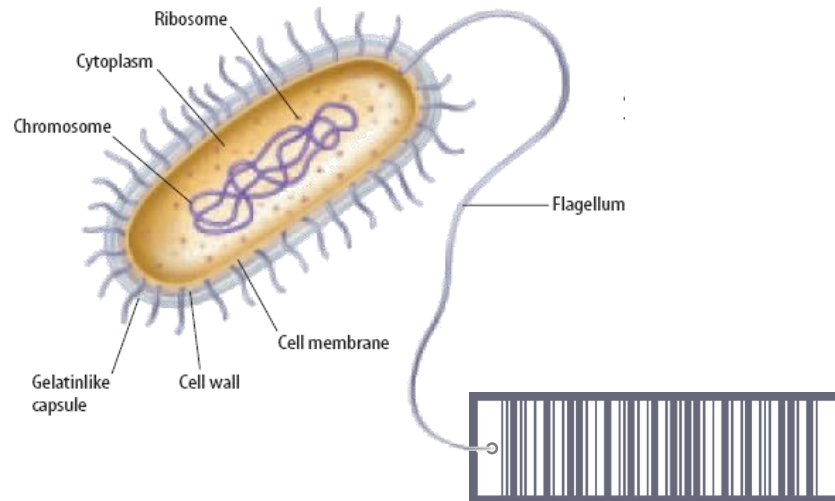

Ridaura *et al.*...Jeffrey Gordon, Science 2013
Walker & Parkhill, Science 2013

16S metagenomics

Problem: most bacterial species can't be cultured

Solution: 16S ribosomal RNA

Woese & Fox, PNAS 1977

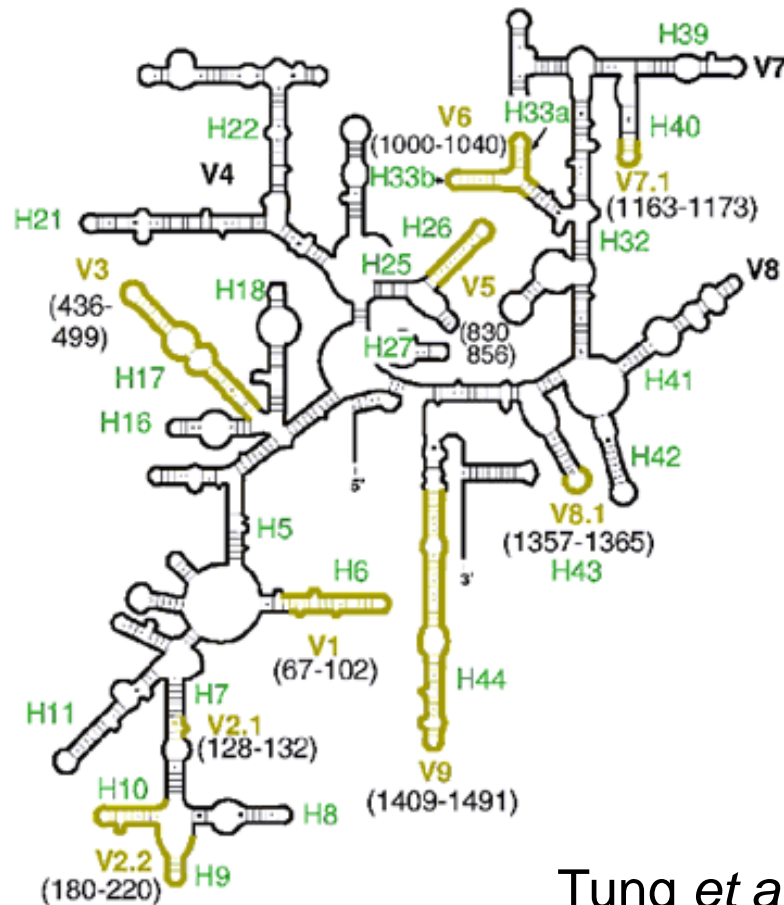

Big questions

- Origin, maintenance, and significance of diversity?
Role of “rare” species
- Factors shaping community?
Environment, interactions, host immunity, chance
- Relation to health and disease?

16S RNA gene

0 100 200 300 400 500 600 700 800 900 1000 1100 1200 1300 1400 1500 bp

Tung *et al.*, Nat Struct Biol 2002

Usual 16S work flow

Data Visualization

Sample

Form OTUs
→

Raw sequence reads

Operational Taxonomic Units (OTUs)

Justification?

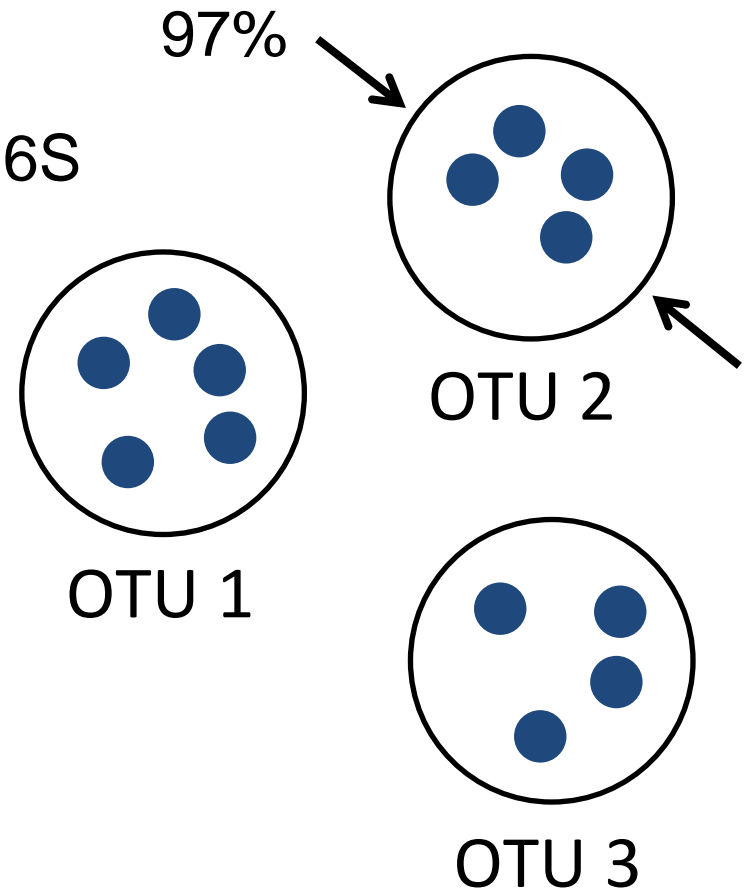

1. Noise
2. Ecological similarity of close 16S

Applications?

1. Mapping to known species
2. Co-occurrence patterns

However, OTUs are ill-defined.

Do we need OTUs?

16S analysis without OTUs

Data: daily sampling of the tongue community of two cohabiting individuals for > 1 year (Caporaso *et al.*, Genome Biol (2011))

Log₁₀ abundance
of 360 neighbors
of Seq. #1
(most abundant
130 nt sequence)

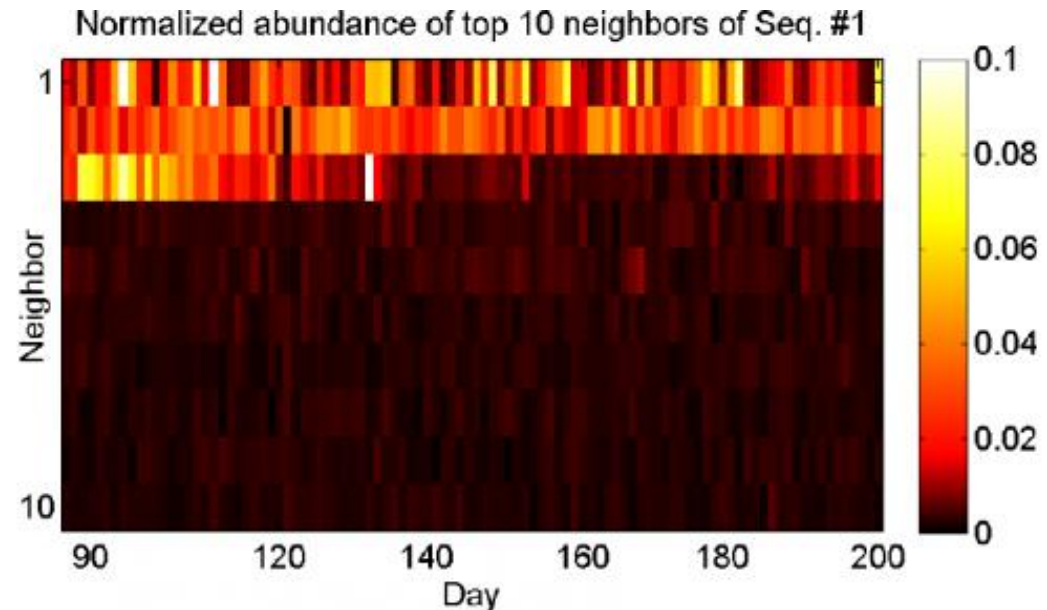

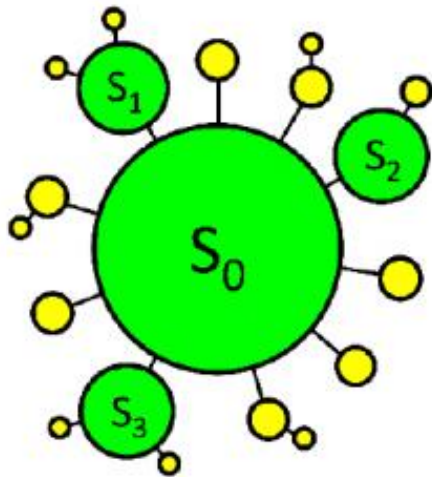

Error rates are low and reproducible

Inferred error rates can be used to identify real sequences

Real sequences differing by only 1 nt have different dynamics

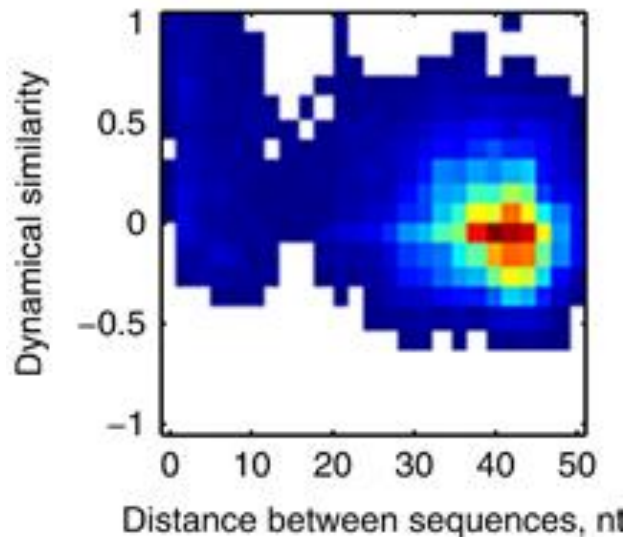

Typically resolve > 20 distinct real sequences per OTU

Dynamical similarity vs. sequence similarity: examples

Dynamical similarity vs. sequence similarity

“Dynamical similarity” = Pearson correlation between time traces
(normalized by maximum possible given Poisson noise)

Same bacterium or a dynamically similar strain?

$\Delta(t)$: Zero 1-day autocorrelation

All difference due to measurement noise

$\Delta(t)$: Nonzero 1-day autocorrelation

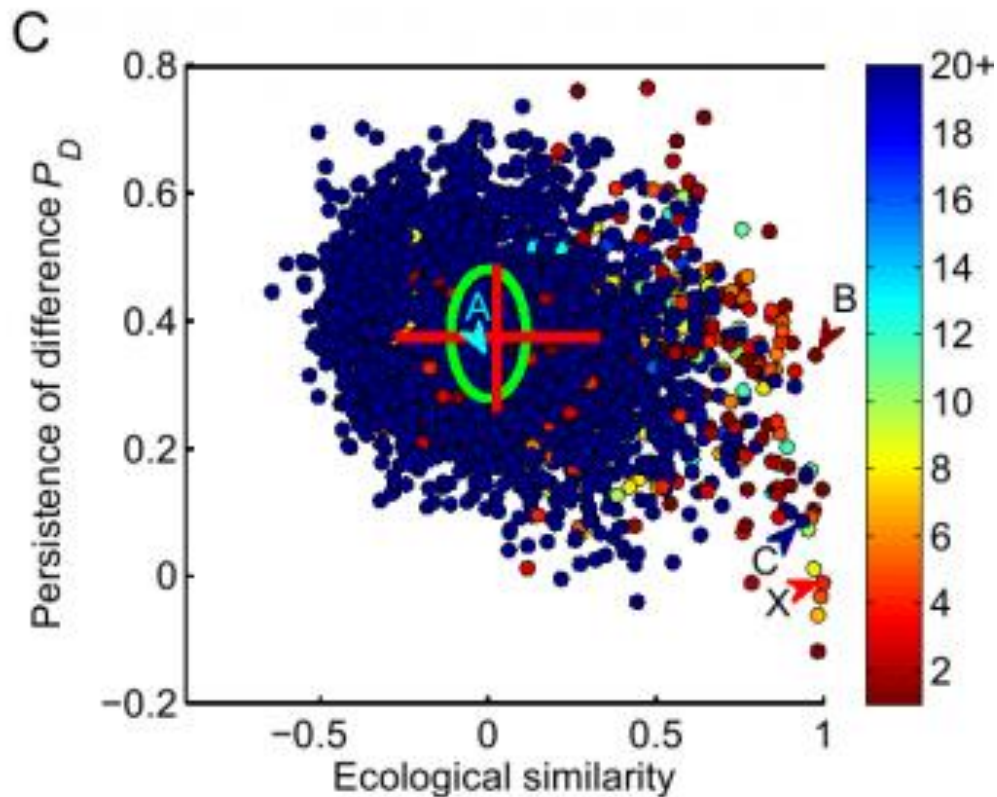

Abundance difference may persist

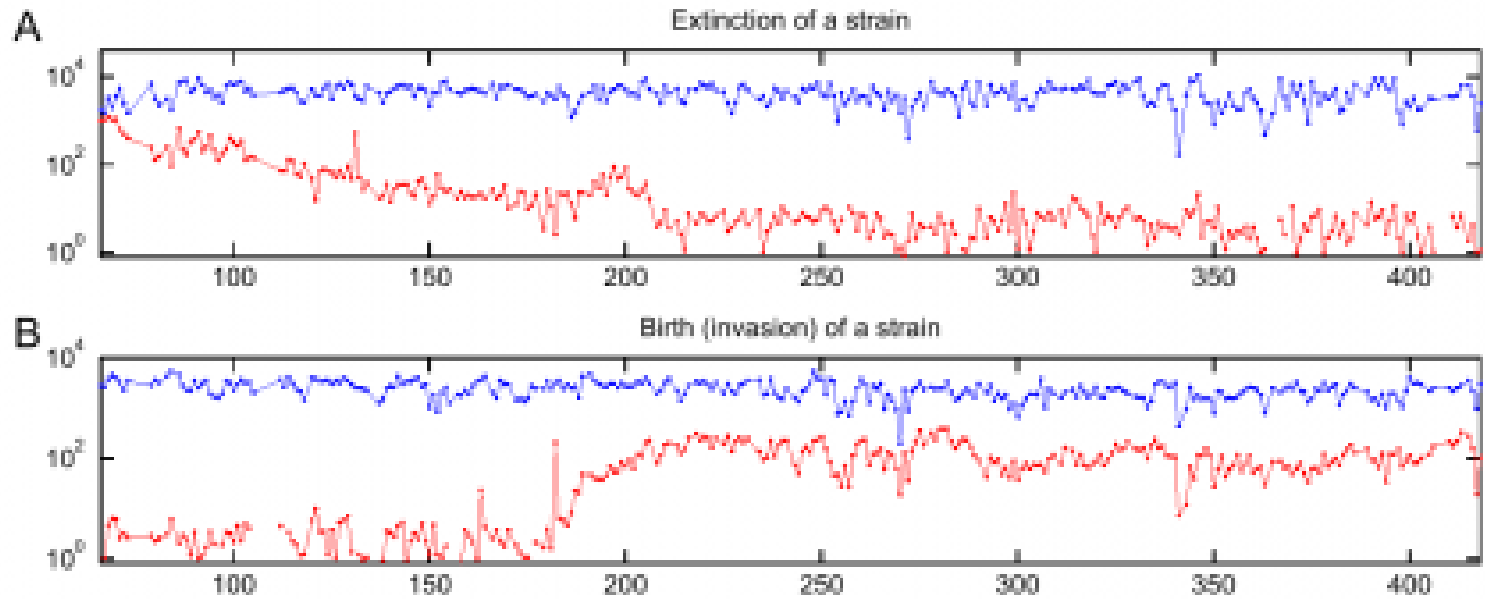

Relative abundance fluctuation $\Delta(t) = (n_2 - n_1) / [(n_1 + n_2)/2]$

“Persistence of difference” $P_D = \langle \Delta(t) \Delta(t+1) \rangle / \langle \Delta^2(t) \rangle$

Can identify 16S paralogs (REPLACE FIGURE!)

Slow dynamics of sequences 1 nt from abundant sequence

Is 130 nt enough?

In principle, distinct subpopulations could share the same 130 nt sequence.

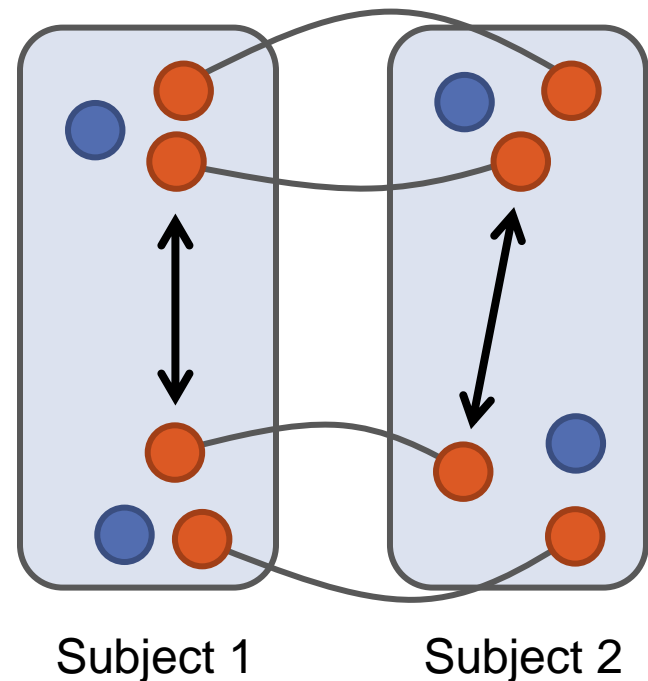

Then exact sequence identity might be no more informative than 1 nt difference, which we know allows for dynamical differences.

What can we do?

Exploit shared strains between two human subjects

Significant strain exchange

Shared strains share dynamical similarity

1 nt mismatch enough to degrade correlation of dynamical similarity

16S tag identity and near-identity are fundamentally different

Near-identity:

$\sim 10^6$ generations

16S tags differ by 1 nt

Identity:

16S tags identical

or, more likely,

Summary and conclusions

- Microbiomes are ubiquitous – bacteria live in communities
- Metagenomics: rich source of data (16S and “shotgun”)
- Cluster-free filtering for time-series & multi-sample 16S data
- Applied to tongue microbiome data (Caporaso *et al.* (2011)):
 - 20+ real sequences per OTU
 - 16S paralogs vs. dynamically similar strains
 - Slow dynamics of subpopulations
- Many big questions to address...
